## Capillary Fill Time \& Meniscus Shape:

A non-symmetric, non-equal contact angle, coplanar cavity study

Matt Colburn
Surface Phenomena Project
December 1, 1998

## Problems:

. What is the shape of the meniscus as it traverses a wavy cavity?

- How does the fluid properties and the system geometry affect the fill time?

## Motivation:

- Nanoimprint lithography techniques under development at UT, Harvard, Princeton require a fluid to fill a cavity that is not planar.
- Production speeds require a fill time of $\sim 1$ second.

## What is the surface tension contribution?

I How does the fluid affect is?
\| Rate of Fill $\propto 1 / \mu$
$\|$ Rate of Fill $\propto \gamma$
. How does the "wavy" surface affect it?
\| Requires more insight into the geometry!!!

## Fill Time Prediction:

I. Washburn Equation for Cylindrical Capillary

$$
\frac{d x}{d t}=\frac{2 \pi R \gamma \cos \theta+\pi R^{2} P}{8 \pi \mu x}
$$

- Washburn Equation for Planar Cavity

$$
\frac{d x}{d t}=\frac{(\gamma / R)}{(24 \mu x) / H^{2}}
$$

## Model System:

Fluid Properties: $\mu, \theta_{1}, \theta_{2}, \gamma$

## Model Assumptions:

II Constant Contact Angles
\| Newtonian Fluid

- Constant Density
\| Pressure at Inlet $\propto$ Height of Feed
- Height of Feed $\propto$ Volume of Cavity

## Assumptions Con't:

| Experimental System | Model |
| :--- | :--- |
| $1: 1: 1$ solvent: monomer: polymer | Nextonian Fluid of constant viscosity and <br> density |
| Top plate has anisotropic etched pattern of <br> depth, $2_{\alpha^{c}}$ and period, $\lambda$. | Sinusoidal pattern of amplitude,,$\infty$ and <br> wavelength, $\lambda$ |
| Plates are 1 square inch. | Plates of length (L), 2.5 cm Neglect Edge <br> effects. |
| Slightly non-coplanar plates | Coplanar plates |
| $0^{\circ}<\theta_{1}<30^{\circ}$ <br> $50^{\circ}<\theta^{\circ}<90^{\circ}$ | $\theta^{1}=30^{\circ}$ <br> $\theta^{\circ}=60^{\circ}$ |
| Fluid feed by a convex drop of radius R' on <br> one edge. | Fluid feed with fluid height, D. Initially D $=$ <br> $L^{*} H / 1$ microns |

## Defined Surfaces:

## Upper Surface

$$
s(t)=t \vec{i}+\left(H+\alpha \sin \left(\frac{2 \pi x}{\lambda}\right)\right) \vec{j}
$$

Lower Surface

$$
g(\gamma)=\gamma \vec{i}
$$

Meniscus

$$
\eta(\beta, \gamma)=\left(x_{c}(\gamma)+R \cos (\beta)\right) \vec{i}+\left(y_{c}(\gamma)+R \sin (\beta)\right) \stackrel{\rightharpoonup}{j}
$$

## Model Method: A Shooting Approach

- Increase radius until the meniscus and the upper surface touch.
- Calculate the dot product and check constraint is met.

## Model Constraints:

II Contact Angles, $\theta_{1} \& \theta_{2}$ must be met.

$$
\begin{gathered}
\cos \theta_{2}=-\frac{\left[(2 \pi \boldsymbol{A} / \lambda) \cos \beta_{s} \cos \left(\frac{2 \pi t}{\lambda}\right)-\sin \beta_{s}\right]}{\left[1+((2 \pi \boldsymbol{A} / \lambda) \cos (2 \pi t / \lambda))^{2}\right]^{1 / 2}} \\
\cos \left(\theta_{1}\right)=-\sin \left(\beta_{1}\right)
\end{gathered}
$$

## Radius Along Path II:

Radius of Curvature Along Length of Cavity

## Radius Along Path:

Radius of Curvature During Fill

$$
H=0.2, \alpha=0.1, \lambda=0.2
$$

## Meniscus Shape During Fill:

Meniscus Shape During Fill Time

Position Along Cavity

## Added Complexity: Multiple Solutions

Multiple solutions to Meniscus Shape

$$
\mathbf{H}=1.0, \alpha=0.1, \lambda=0.2
$$

## Minimum Radius Solution:

Meniscus Shape During Fill With Minimum Radius Solution

Position Along Cavity

## Meniscus Location During Fill

Location of Meniscus During Fill Process

$$
\mathrm{H}=1 \mu \mathrm{~m}, \alpha=0.1 \mu \mathrm{~m}, \lambda=0.1 \mu \mathrm{~m}
$$

## Fill Time For Different Viscosities \& Surface Tensions:

Fill times (seconds)

| Viscosity $(P)$ | $H=1, \alpha=0.1, \lambda=0.2$ | $H=1, \alpha=0.1, \lambda=0.1$ | $H=0.2, \alpha=0.1, \lambda=0.2$ | $H=0.2, \alpha=0.1, \lambda=0.1$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.001 | 28.56 | 15.12 | 112 | 56 |
| 0.01 | 285.6 | 151.2 | 1120 | 560 |
| 0.1 | 2856 | 1512 | 11200 | 5600 |
| 1 | 28560 | 15120 | 112000 | 56000 |

Fill times (seconds)

| Viscosity | $\gamma=30$ dynes $/ \mathrm{cm}$ | $\gamma=50$ dynes $/ \mathrm{cm}$ | $\gamma=70$ dynes $/ \mathrm{cm}$ |
| :---: | :---: | :---: | :---: |
| 0.01 | 8 | 4.8 | 3.4 |
| 0.1 | 80 | 48 | 34.3 |
| 1 | 800 | 480 | 342.9 |

Lower $\mu$, higher $\gamma$, small $\lambda$ provides fastest fill time.

Unsatisfactory for production photolithography rates.

## Fill Time:

## Viscosity \& Surface Tension Effect on Fill

Viscosity (P)

Surface Tension (dyne/cm)

| $\square 80000-100000$ |
| :--- |
| $\square 60000-80000$ |
| $\square 40000-60000$ |
| $\square 20000-40000$ |
| $\square 0-20000$ |

Fill Time (sec)

## Conclusions:

- Smaller wavelengths fill faster than longer wavelengths due to affects on radius of curvature.
- Higher surface tension and lower viscosity improve fill times.
- Considering only capillary action, fill times are too slow for production use.

## Future Improvements:

\|Improve computational time.
I Eliminate contact angle dependence, use specific surface energies of different surfaces to predict performance.

- Look at free energy of entire system as it traverses the cavity.
I Add non-uniformity of surface energy along treated wavy surface.
