

The Claisen Condensation

March 29, 2016

Exam Tomorrow Evening!!

Review tonight 5PM -6PM Welch 1.316

Some "loose ends" before we go on

Spectrosopy of acid derivatives
 A selective reduction for your tool box

Reduction of Acid Derivatives

- Acids (page 679-681)
- Esters (page 738-739)
- Please work through the example on 738
- Amides (page 739-742)
- Nitriles (page 742)
- Selective reductions with NaBH₄

DIBAIH

Disobutylaluminum hydride (DIBAIH) at -78°C selectively reduces esters to aldehydes

 at -78°C, the tetrahedral intermediate does not collapse and it is not until hydrolysis in aqueous acid that the carbonyl group of the aldehyde is liberated

Infrared Spectroscopy

C=O stretching frequency depends on whether the compound is an acyl chloride, anhydride, ester, or amide.

Infrared Spectroscopy

Anhydrides have two peaks due to C=O stretching. One from symmetrical stretching of the C=Oand the other from an antisymmetrical stretch.

C=O stretching frequency v O O || || CH₃COCCH₃

1748 and 1815 cm⁻¹

Infrared Spectroscopy

Nitriles are readily identified by absorption due to carbon-nitrogen triple bond stretching that is "all alone" in the

<u>2210-2260</u> cm⁻¹ region.

Hydrolysis and Decarboxylation

t-Butyl esters

t-Butyl esters

t-Butyl ester hydrolysis

Recall our discussion of the acidity of protons α to carbonyls

- The anion is stabilized by resonance
- The better the stabilization, the more acidic the a proton
- Acidity of a protons on "normal" aldehydes and ketones is about that of alcohols and less than water...pKa ~ 18-20
- Some are far more acidic, i.e. β-dicarbonyl compounds that have quite low pKa's

 Rainer Ludwig Claisen (1851-1930): Born in Köln and studied chemistry at Bonn, and briefly at Göttingen. He earned his doctorate at Bonn under August Kekulé (1829-1896).

Classical Claisen Condensation $\begin{pmatrix} 0 \\ 1 \\ 2CH_{3}COCH_{2}CH_{3} \\ 2. H_{3}O^{+} \end{pmatrix}$

 Two moles of ethyl acetate condense to give ethyl acetoacetate or (acetoacetic ester)

Chemistry 328N

Step 1:

The enolate anion is stabilized by resonance

:O: $CH_2 = COCH_2CH_3$ $:CH_2 / COCH_2 CH_3$

Chemistry 328N

Step 2: Nucleophilic acyl substitution

Step 2:

Step 3:

- The product is ethyl acetoacetate.
- However, were nothing else to happen, the yield of ethyl acetoacetate would be small because the equilibrium constant for its formation is small.
- Something else <u>does</u> happen. Ethoxide abstracts a proton from the CH₂ group to give a stabilized anion. The equilibrium constant for this acid-base reaction is very favorable.

 Two moles of ethyl acetate condense to give ethyl 3-oxobutanoate or ... ethyl acetoacetate aka acetoacetic ester

Crossed Claisen Condensation

• What is wrong with this?

 $\begin{array}{c}
\mathsf{O} \\
\mathsf{I} \\
\mathsf{I} \\
\mathsf{CH}_3 \mathsf{CH}_2 \mathsf{C} \mathsf{O} \mathsf{CH}_2 \mathsf{CH}_3 + \mathsf{CH}_3 \mathsf{C} \mathsf{O} \mathsf{CH}_2 \mathsf{CH}_3
\end{array}$

No No No...it gives a mixture of products, a big fat mess!!

Crossed Claisen Condensation

Crossed reactions can work if one does it carefully and one of the reactants does not have an alpha hydrogen such as:

Chemistry 328N

Crossed Claisen Condensation -- An Example

Chemistry 328N

Crossed Claisen Condensation

Crossed Claisen condensations between two different esters, each with α -hydrogens, give bad mixtures. They are not useful and will not be accepted as legitimate answers in our class

You can do this if you use one component with no α-hydrogen <u>and</u> if you run the reaction properly

- How would YOU run the reaction??
- What sequence of additions?
- What stoichiometry?
- What base?

Deprotonation of Simple Esters

- Ethyl acetoacetate (pKa ~11) is "completely" deprotonated by alkoxide bases.
- Simple esters (such as ethyl acetate) are not completely deprotonated, the enolate reacts with the original ester, and Claisen condensation occurs.

 Do there exist bases strong enough to completely deprotonate simple esters, giving ester enolates quantitatively?

Lithium diisopropylamide (LDA)

$$\begin{array}{ccc} CH_{3} & CH_{3} \\ I & I \\ C & N \\ I \\ CH_{3} \\ CH_{3} \\ CH_{3} \end{array}$$

- LDA is a strong base (just as NaNH₂ is a very strong base). pKa ~36
- Because it is so sterically hindered, LDA does not add to carbonyl groups.

Lithium diisopropylamide (LDA)

 LDA converts simple esters quantitatively to the corresponding enolate.

 $CH_3CH_2CH_2CCH_3 + LiN[CH(CH_3)_2]_2$

p*K*_a ~ 22

 O_{1} $CH_{3}CH_{2}CHCOCH_{3} + HN[CH(CH_{3})_{2}]_{2} + Li^{+}$ $pK_{a} \sim 36$

Chemistry 328N

Lithium diisopropylamide (LDA) Enolates generated from esters and LDA can be alkylated.

Intramolecular Claisen Condensation: The Dieckmann Reaction

0: CH₃CH₂OCCH₂CH₂CH₂CH₂COCH₂CH₃ NaOCH₂CH₃ CH₃CH₂OCCH₂CH₂CH₂CHCOCH₂CH₃

Ö: CH₃CH₂OCCH₂CH₂CH₂CH₂CHCOCH₂CH₃

A versatile synthesis of β-ketoesters and <u>symmetrically</u> substituted acetones

Alkylation of Acetoacetic Ester gives unsymmetrically substituted acetone

Acetoacetic Ester Synthesis

Ketone Synthesis

Let's work another example together
